# 'C' Reversing

nafiez

# Basic to brother!

Data Types	Bytes
char	1 byte
short	2 bytes
int	4 bytes (platform word)
long	4 bytes
float	4 bytes floating point
double	8 bytes floating point

# Arrays

# Example

#### C code

char val[2][3][2] = { { (0', '1'}, {'2', '3'}, {'4', '5'} } };

## Assembly

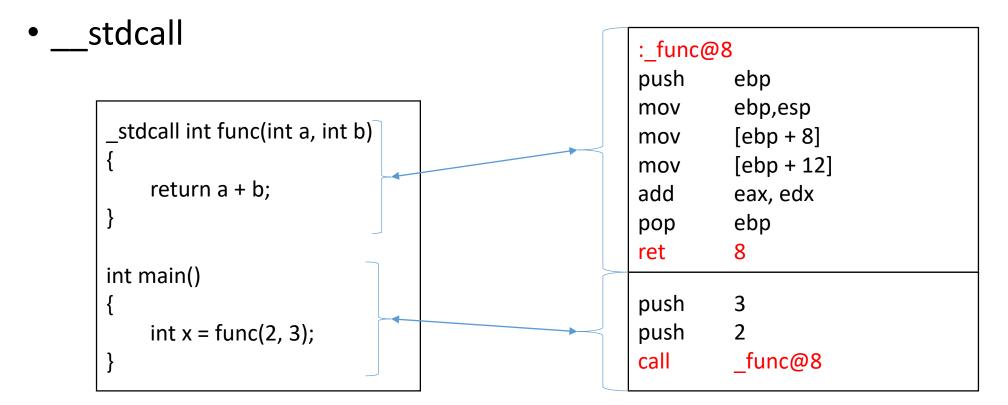

```
mov [ebp + val], '0'
mov [ebp + val + 1], '1'
mov [ebp + val + 2], '2'
mov [ebp + val + 3], '3'
mov [ebp + val + 4], '4'
mov [ebp + val + 5], '5'
```

# Calling Conventions

- Methods for function to be implemented and called by machine
- Specify how arguments are passed to a function
- Basically its about specifying how a function call in C / C++ converted into assembly.
- In Visual Studio, there few types of calling conventions (we focused on x86 processors):
  - STDCALL
  - CDECL
  - FASTCALL

## STDCALL

Used to call WIN32 API functions

### FASTCALL

- Specifies arguments to functions are to be passed in registers
- fastcall

```
:@func@8
_fastcall int func(int a, int b)
                                                     push
                                                               ebp
                                                              ebp,esp
                                                     mov
    return a + b;
                                                              eax, edx
                                                     add
                                                               ebp
                                                     pop
                                                     ret
int main()
                                                               eax, 2
                                                     mov
    int x = func(2, 3);
                                                               edx, 3
                                                     mov
                                                               @func@8
                                                     call
```

## CDECL

Default calling convention for C / C++ programs

```
cdecl
                                                        func:
                                                      push
                                                                ebp
                                                               ebp,esp
                                                      mov
  _cdecl int func(int a, int b)
                                                               [ebp + 8]
                                                      mov
                                                               [ebp + 12]
                                                      mov
      return a + b;
                                                               eax, edx
                                                      add
                                                                ebp
                                                      pop
                                                      ret
 int main()
                                                      push
                                                                3
      int x = func(2, 3);
                                                      push
                                                                _func
                                                      call
                                                      add
                                                                esp, 8
```

## Passing Arguments

- Calling function writing to data in place where the called will look for them.
- Arguments are passed before call instruction is executed.
- Right-to-Left (R2L) and Left-to-Right (L2R)
  - Arguments are passed in subroutine

# Example: R2L & L2R

Generated code push a push b call \_MyFunction Left-to-Right MyFunction(a, b); High-level code in C push b push a Call \_MyFunction Generated code Right-to-Left

### Return Value

- If functions returns a value, it will reliably received by function's caller.
- Called function stores the return value before executing *ret* instruction.

# Stack Cleaning (Caller-Callee)

- Arguments push onto stack, and it will need to pop out from the stack.
- Caller-Callee responsible to do cleaning in the stack (reset the stack pointer) to eliminate passed arguments.
- Caller
  - Parent function calls subroutine. Execution resumes in the calling function after subroutine call, unless it terminated inside the subroutine
- Callee
  - child function called by parent
